Motivation

Effects of Interest

1. What we want

- Estimate: Effect of binary or treatment variable on binary outcome variable
- ► Treatment variable itself is endogenous
- ▶ Unobservables may correlate with treatment and outcome equation
- Compute average treatment effect
- Compute average marginal effect for covariates

2. What doesn't work:

- margins gives incorrect treatment effect
- margins gives incorrect average marginal effect for covariates
- ivprobit inapproriate; treatment variable is binary

3. What we need

- Correct Estimation of a RBPM
- ▶ Considering recursive nature of the model for postestimation commands

August 5-6, 2021 2021 Stata Conference Mustafa Coban 3 / 35

Contribution

A new Stata Command

- ▶ rbprobit estimates RBPMs like biprobit or cmp
- rbprobit accounts for recursive nature in postestimation commands
 - predict and predictnl
 - margdec
 - tmeffect
- margdec incorporates margins command, enabling
 - Decomposition of average marginal effects of covariates
 - Standard errors using the delta method
- tmeffect incorporates margins command, enabling
 - Different definitions of treatment effects
 - Standard errors using the delta method

Recursive bivariate probit model

The Model

A structural model with endogenous explanatory treatment variable y_2 correlated with the unobservables

$$y_1^{\star} = \boldsymbol{x'}\boldsymbol{\beta} + \alpha y_2 + \epsilon_1 \quad , y_1 = 1 \Big[y_1^{\star} > 0 \Big]$$
 (1)

$$y_2^{\star} = \boldsymbol{z'} \boldsymbol{\gamma} + \epsilon_2$$
 , $y_2 = 1 \left[y_2^{\star} > 0 \right]$ (2)

with
$$\begin{pmatrix} \epsilon_1 \\ \epsilon_2 \end{pmatrix} \sim \mathcal{N} \left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix} \right]$$

- \blacktriangleright correlation between ϵ_1 and ϵ_2 induces the endogeneity
- x and z can share some or all covariates
- lacktriangle Greene (2018) notes that endogenous nature of y_2 can be ignored
- lacktriangle Han and Lee (2019): estimates are at best weakly identified if x=z

 August 5-6, 2021
 2021 Stata Conference

Recursive bivariate probit model

Treatment Effects

1. Average Treatment Effect (ATE)

$$ATE = \frac{1}{n} \sum_{i=n}^{n} \Phi(x_i'\beta + \alpha) - \Phi(x_i'\beta)$$

2. Average Treatment Effect on the Treated (ATT)

$$\mathsf{ATT} = \frac{1}{n_2} \sum_{i=1}^{n_2} \Phi\left(\frac{x_i'\beta + \alpha - \rho z_i'\gamma}{\sqrt{1 - \rho^2}}\right) - \Phi\left(\frac{x_i'\beta - \rho z_i'\gamma}{\sqrt{1 - \rho^2}}\right) \quad \forall \ y_{2i} = 1$$

3. Average Treatment Effect on Conditional Probability (ATC)

$$\mathsf{ATC} = \frac{1}{n} \sum_{i=1}^n \frac{\Phi_2(x_i'\beta + \alpha, z_i'\gamma, \rho)}{\Phi(z_i'\gamma)} - \frac{\Phi_2(x_i'\beta, -z_i'\gamma, -\rho)}{\Phi(-z_i'\gamma)}$$

Decomposition of Marginal Effects

Joint and Conditional Probabilities

- lacktriangle Covariate d appears in both $oldsymbol{x}$ and $oldsymbol{z}$
- Decomposition of total marginal effects on the probabilities (except marginal probabilities) are then
 - 1. Continuous Variables (see Greene, 2018)

$$\mathsf{ME} = \frac{\partial \Pr}{\partial \begin{pmatrix} x_d \\ z_d \end{pmatrix}} = \underbrace{\frac{\partial \Pr}{\partial x_d}}_{\text{direct effect}} + \underbrace{\frac{\partial \Pr}{\partial z_d}}_{\text{indirect effect}}$$

2. Discrete Variables (see Hasebe, 2013; Edwards et al., 2019)

$$\mathsf{ME} = \underbrace{\left[\Pr|_{x_d=1} - \Pr|_{x_d=0}\right]}_{\mbox{direct effect}} + \underbrace{\left[\Pr|_{z_d=1} - \Pr|_{z_d=0}\right]}_{\mbox{indirect effect}}$$

Basic Syntax

```
rbprobit depvar [=] [indepvars] [if] [in]
, endogenous(depvar_en [=] [indepvars_en])
```

- depvar_en automatically added to outcome equation as factor-variable
- rbprobit implemented as an lf1 ml evaluator
- depvar and depvar_en have to be binary (current version)
- ▶ factor variables and time-series operators allowed
- rbprobit postestimation available for features after estimation

Predictions of Interest

1. Joint Probabilities

$$Pr(y_1 = 1, y_2 = 1 | x, z) = \Phi_2(x'\beta + \alpha, z'\gamma, \rho)$$

$$Pr(y_1 = 1, y_2 = 0 | x, z) = \Phi_2(x'\beta, -z'\gamma, -\rho)$$

$$Pr(y_1 = 0, y_2 = 1 | x, z) = \Phi_2(-x'\beta + \alpha, z'\gamma, -\rho)$$

$$Pr(y_1 = 0, y_2 = 0 | x, z) = \Phi_2(-x'\beta, -z'\gamma, \rho)$$

2. Conditional Probabilities

$$\Pr(y_1 = 1 | y_2 = 1, x, z) = \frac{\Phi_2(x'\beta + \alpha, z'\gamma, \rho)}{\Phi(z'\gamma)}$$
$$\Pr(y_2 = 1 | y_1 = 1, x, z) = \frac{\Phi_2(x'\beta + \alpha, z'\gamma, \rho)}{\Phi(x'\beta + \alpha)}$$

Predictions of Interest

3. Marginal Probabilities

$$Pr(y_1 = 1|x) = \Phi(x'\beta + \alpha y_2)$$

$$Pr(y_2 = 1|z) = \Phi(z'\gamma)$$

4. Unconditional Mean Function (see Blasch et al., 2019; Alrasheed, 2019)

$$\begin{split} E[y_1|x,z] &= \Pr(y_2 = 1|z) \cdot E[y_1|y_2 = 1,x,z] \\ &+ \Pr(y_2 = 0|z) \cdot E[y_1|y_2 = 0,x,z] \\ &= \Pr(y_1 = 1,y_2 = 1|x,z) + \Pr(y_1 = 1,y_2 = 0|x,z) \\ &= \Phi_2(x'\beta + \alpha, z'\gamma, \rho) + \Phi_2(x'\beta, -z'\gamma, -\rho) \end{split}$$
